### Abstract

The methods of potentiometric titration and NMR relaxation were used to study the influence of the nonionic surfactant (NS), namely Triton X-100 (TX), on the acid-base and complexing properties of salicylic (H2L), benzoic (HR), and sulfosalicylic (H3X) acids. The influence of NS added on the titration curves of the examined acids was analyzed and it was established that salicylic and benzoic acids are bound by micelles to form species (H2L(TX)) and (HR(TX)) with  $\log K$  equal to  $2.12 \pm 0.03$  and  $1.57 \pm 0.03$ , respectively. The acidic properties of H3X are virtually the same in water and in the NS solutions. A significant (more than two-fold) increase in the proton relaxation rate is observed in the solutions of the mixtures of salicylic acid and TX in the presence of  $\text{Cu}^{2+}$ ,  $\text{Mn}^{2+}$ , or  $\text{Gd}^{3+}$  ions. This effect was explained by the formation of ternary cation-ligand-surfactant species. For Cu(II) and Mn(II), compounds  $\{\text{M}(\text{HL})_2(\text{TX})_2\}$  with  $\log K$  equal to  $0.90 \pm 0.04$  and  $1.05 \pm 0.04$ , respectively, were detected. Complexes of composition  $\{\text{Gd}(\text{HL})_3(\text{TX})_2\}$  with  $\log K = 0.22 \pm 0.05$  were discovered for Gd(III). The ternary species of benzoic acid are formed only in the presence of gadolinium: (GdR(TX)) with  $\log AT = -2.17 \pm 0.04$ . Sulfosalicylic acid does not form such mixed NS-containing compounds with the cations examined. © 1998 MAK Haya/Interperiodica Publishing.
